

Proteomics

31.10.2023

PD Dr. Katja Bärenfaller

katja.baerenfaller@siaf.uzh.ch

After this lecture, you will be able:

- to recognize and describe the significance of protein characterization
- to explain the principle of a mass spectrometry-based experiment
- to apply the principle of *de novo* peptide spectrum matching
- to describe the principle of database-dependent peptide spectrum matching
- to calculate the false discovery rate based on a target decoy approach
- to describe various application methods of proteomics

➢ Buzz group (7 min):

Discuss in groups of two or three why examining proteins is important and what information can be gained (only) through the direct characterization of proteins.

Proteomics is the large-scale study of proteins and the proteome, which is the entire set of proteins produced or modified by an organism or system.

Proteomics includes the study of:

- protein roles, structures, quantities, localization, and functions
- post-translational modifications (and their change)
- protein interactions with DNA, RNA, other proteins, etc.

and how all these change in time, between conditions or in response to stimuli

Why proteome research?

Why proteome research?

- It is primarily the proteins, their activities, modifications, subcellular localization, and interactions that are responsible for determining the appearance and state of a biological organism.
- Various processes determine protein levels and activities

The abundance and activitiy of proteins can not be automatically inferred from transcript levels due to the complexity of gene expresssion regulation.

Baerenfaller et al., 2012

Translational coincidence mechanism

- Quantitative protein and transcript data of
 Arabidopsis in four different photoperiods
 have revealed that proteins with clockregulated, evening-peaking RNAs tended
 to increase in abundance under longer
 daylengths, whereas proteins with
 morning-peaking RNAs did not.
- A simple, "translational coincidence" model predicted the experimental results, because high, light-induced translation rates will coincide with high levels of an evening-expressed RNA only under long days, not short days.
- Many clock-controlled genes might gain seasonal control of protein levels via translational coincidence.

Why proteome research?

An example of a non mass spectrometry-based proteomics approaches

Generic mass spectrometry-based proteomics experiment

Enzymatic digestion

Radzikowska et al., Omics technologies in allergy and asthma research: An EAACI position paper, Allergy, 2022

- Before analysis, the proteins are typically digested with a site specific protease, most of the time with trypsin.
- Trypsin cuts after arginine or lysine, except when the cutting site is followed by proline, which leads to limited cleavage.

- After protein cleavage, the peptides need to be purified.
- The peptides are often fractionated or enriched for specific features such as specific posttranslational modifications, internal cleavage sites, etc.

Liquid chromatography separates the mixture of peptides based on the principle of partitioning of solutes between two phases.

In reverse phase (RP) chromatography, the separation uses a column (non-polar stationary phase) and solvent (gradient of a mixture of a polar and a non-polar mobile phase); the components are separated from each other based on their affinity for the stationary phase depending on the polarity of the mobile phase that is changing over time.

The goal of the separation is to find the best compromise between resolving the components over time and having sharp and intense elution peaks.

Chromatogram of a reverse phase column chromatography

Ion Generation - Electrospray Ionization (ESI)

MS Spectrum

Identifying peptides using an MS spectrum:

Peptide spectrum assignment with Peptide Mass Fingerprinting is only advisable with samples of low complexity and small sequence databases, as the number of all possible peptides with a given mass over charge is huge in large sequence databases.

Tandem Mass Spectrometry (MS/MS)

• Obtaining sequence information for a peptide ion:

MS/MS spectrum

The isotope issue

- 1/100 C atoms is C13
- The more atoms a peptide contains, the more probably it is that one to several C atoms are C13

Peptide spectrum assignment

- The most common peptide fragments observed in low energy collisions are **a**, **b** and **y** ions.
- The **b** ions appear to extend from the amino terminus (N-terminus), and **y** ions appear to extend from the carboxyl terminus (C-terminus).
- **a** ions occur at a lower frequency and abundance in relation to **b** ions.

adjusted from http://www.ionsource.com/

$$P - I - D - T - R$$

m/z = 601.31

Masses of b- and y- ions:

b-ions				y-ions	
		PIDTR	601.31	y5	
b1	98.05	P IDTR	504.26	y4	
b2	211.14	PIDTR	391.18	уЗ	
b3	326.16	PID TR	276.15	y2	
b4	427.21	PIDTR	175.10	y1	
b5	583.31	PIDTR			

Fragment masses aligned along a spectrum graph:

Hypothetical fragment spectrum

Analysing a spectrum for the fragments

m/z

In *de novo* peptide sequencing, all information about the peptide sequence resides in the MS/MS spectrum itself. It is therefore database-independent and can be done manually or with algorithms.

Manual de novo peptide sequencing:

- M = Mass of the peptide
- **Precursor ion** $M_{Precursor} \cong \frac{(M + 2H)^{2+2}}{2}$
- •Parent ion $M_{Parent} \cong (M+H)^{+}$

$$M_{Parent} = M_{Precursor} * 2 - 1 = \frac{(M+2H)^{2^+}}{2} * 2 - 1$$

• Monoisotopic mass of the parent ion

$$M_{Parent mono} = M_{Parent average} - \frac{M_{Parent average}}{1463}$$

• b- and y- ions:

Zubarev and Bondarenko, 1991

$$y = (M+H)^{+}-b + 1$$
; $b = (M+H)^{+}-y + 1$

•Find the b-ion without the C-terminal K or R: (M+H)⁺ - 18 ('lost' oxygen) – [KR]

'Lost' oxygen

- > Upon peptide bond formation, H_2O gets released and this mass is therefore not included in the Δ mass for the individual amino acids
- The largest b-ion is mass of the parent ion 18, because H₂O gets released and the positive charge resides at the C-terminus

E:\XCalibur\data\20070130_11_ppi1_B1

2

Neutral losses and peptide modifications

- Neutral losses
- H₂0 (-18 Da)
- NH₂ (-17 Da)
- CO (-28 Da)
- H₃PO₄ (-98 Da)
- Modifications
- Oxidation: M +16 Da
- Deamidation: $N \rightarrow Q$, -1 Da
- Methylation: R +14 Da
- Phosphorylation: S, T, Y +80 Da
- Acetylation: K, R, N-terminus +42 Da
- Carboxyamidomethylation: C +57 Da

Given the following peptide with the indicated fragment ions,

- 1) What ions will change their m/z when Serin 7 will be phosphorylated?
- 2) What ions will change their m/z when the peptide N-terminus is acetylated?
- 3) What ions will change their m/z when the C-terminal lysine is isotopically labeled?

https://pwa.klicker.uzh.ch/join/kbaere

- 1. Dynamic programming
 - The algorithms suffer from 'real life issues' of peptide mass spectrometry, e.g. they are sensitive against noisy data
 - Requires pre-processing of the information in an MS/MS spectrum
- 2. Hidden Markov Models
 - Fully probabilistic
 - Can deal with noisy data
- → Studies comparing the performance of *de novo* sequencing algorithms revealed that the rate of exact peptide sequence identification is low with high error rate
- → Problems for *de novo* sequencing are limited mass accuracy of the mass spectrometers, missing ions, unknown identity of the peaks and additional, sequence-independent peaks

Different database-dependent peptide identification search algorithms:

- Sequest
- Mascot
- PepSplice
- OMSSA
- X!Tandem
- Phenyx
- ProteinPilot
- SpectrumMill
- ProbID
- PepFrag
- InSpect

. . .

٠

- Peptide sequences with one or more scores with which to evaluate the likelihood that the resulting sequence is correct.
- Even though each implementation is different, they operate under the same general principle.

Database-dependent peptide identification

- The goal is to identify the best sequence match to the spectrum
- The details of this implementation differ among the algorithms. In addition, the methods used to assign scores are very different.
- Four basic approaches have been developed to model matches to the sequences: descriptive models, interpretative models, stochastic models and statistical and probability models (Sadygov, Cociorva and Yates, 2004)

Descriptive algorithms are based on a mechanistic prediction of how peptides fragment in a tandem mass spectrometer, which is then quantified to determine the quality of the match between the prediction and the experimental spectrum. Mathematical methods such as correlation analysis have been used to assess match quality.

- Sequest is an example of a program using a descriptive model:
 - S_p, sums the peak intensity of fragment ions matching the predicted sequence ions and accounts for the continuity of an ion series and the length of a peptide
 - Xcorr, is a cross-correlation score of the experimental and theoretical spectra
 - △Cn gives the normalised difference of Xcorr values between the best sequence and lower-scoring matches and is useful to determine the uniqueness of the match

Sadygov, Cociorva and Yates, 2004

Empirical statistical model to estimate the accuracy of peptide identifications

Task:

Derive a list of identified peptides from database search results carried out with a large number of MS/MS spectra.

- This entails distinguishing correct peptide assignments from false identifications.
- For high-throughput analysis and consistent data analysis a statistical model is needed to assess the validity of peptide identifications made by MS/MS database searches.

PeptideProphet

- PeptideProphet computes for each peptide assignment to a spectrum a probability of being correct.
- A discriminant function analysis is used to combine together any number of database search scores into a single discriminant score that best separates training data into correct and incorrect identifications. The discriminant score F is a weighted combination of the database search scores.

 Bayes' theorem gives the probability that a particular peptide assignment with a specific discriminant score is correct:

p(+|F) = p(F|+)p(+) / (p(F|+)p(+) + p(F|-)p(-))

where p(+|F) = probability that the peptide assignment with discriminant score F is correct

Keller et al., 2002

False positives are a concern and can occur because:

- There is usually a mess of peaks observed in a fragment spectrum, which is a reflection of the population of fragment ions produced in the collision cell of a mass spectrometer (not only b and y ions are produced)
- Spectra can be single peptide ions, chemical noise, non-peptide molecules for mixtures of co-eluting isobaric peptides
- Peptides are often present at a wide range of concentrations in a sample, and peptides present at the limit of detection can produce poor quality spectra
- Chemistry of peptide fragmentation is not completely understood
- There are amino acid sequences that do not produce a unique fragmentation pattern but share enough of the same fragment ions to be indistinguishable from one another

1. All the spectra are searched against a database that consists of the target database concatenated to a decoy database (either randomized or reversed target database)

- 1. The hits against the decoy database are clearly wrong as these sequences don't exist
- 2. It can then be assumed that the number of noticeable wrong hits against the decoy database equals the number of non-noticeable wrong hits against the target database

 The estimation of the fdr is a requirement for the analysis and documentation of mass spectrometry data according to the Paris guidelines of Molecular and Cellular Proteomics (Bradshaw, Burlingame, Carr & Aebersold, 2006)

Svozil and Baerenfaller, MIE, 2017

- Global fdrs are calculated for the full dataset
- Local false discovery rates (lfdrs) can be calculated for a subset of the peptide spectrum matches, e.g. the spectra assigned to peptides carrying specific post-translational modifications, or spectra assigned to peptides in an alternative search database, etc.

In a PeptideProphet Search applying a 95% probability cut-off, 1500 spectra were matched to peptides; of these, 30 were matched against peptides from the decoy database.

How many incorrect peptide spectrum matches against the target database do you expect?

Hypothesis-driven, targeted bottom-up proteomics approaches

Radzikowska et al., *Omics technologies in allergy and asthma research: An EAACI position paper,* Allergy, 2022

S/MRM: Selected/Multiple Reaction Monitoring; the proteins are pre-selected and provide information on the characteristic peptide precursor and fragment ion signals (transitions)

DIA/SWATH: Data Independent Acquisition/Sequential Windowed Acquisition of All Theoretical Mass Spectra

PRM: Parallel Reaction Monitoring; similar to S/MRM, but all resulting fragment ion signals from a precursor ion are monitored

Label-free quantification (data dependent analysis DDA)

LC/MS data consist of individual MS spectra accumulated over (retention) time. Stacked side by side, these spectra form two-dimensional maps.

→ In spectral counting the basic assumption is that protein abundance is proportional to the number of spectra (after normalization)
 → Quantification can also be based on the comparison of features, which can be defined as all mass-spectrometric signals (peaks) caused by the same peptide

Workflow for post-translational modifications (PTMs)

Figure 1 in Pascovici et al., Int. J. Mol. Sci. 2019, doi.org/10.3390/ijms20010016

- If PTMs are analysed, the modified proteins or peptides need to be enriched first, as the modified peptides are strongly in the minority
- Searching a lot of variable modifications in your peptide spectrum matching will result in a huge search space and a lot of false positive identifications, so only search for enriched or abundant modifications
- To claim changes in protein/peptide modifications, the PTM data need to be linked to measurements of the total proteome without PTM enrichment

Peptide identification and quantification with Parallel Reaction Monitoring (PRM)

→ With PRM, a set of predefined proteins/peptides can be detected and quantified

SWATH-MS (data independent analysis DIA)

- A) the mass spectrometer steps through a set of precursor acquisition windows
 - In each cycle it fragments all precursors from all the respective quadrupole isolation windows and in each isolation window it records a complete, high accuracy fragment ion spectrum of all precursors
 - The data are analyzed by
 reconstructing the lineage of
 precursor and fragment ions
 based on their
 chromatographic elution
 profile, and with software for
 automated targeted data
 analysis

How to measure thousands of proteome profiles

Christoph Messner Center for Precision Proteomics

Demichev, Messner et al, Nature Methods, 2020

Quantification with labelling: SILAC

a Adaptation phase

b Experiment phase

SILAC = stable isotope labeling by amino acids in cell culture

→ In the adaptation phase, cells are grown in light and heavy SILAC media until full incorporation of heavy amino acids

 \rightarrow In the experimental phase, the two populations are treated differentially to induce changes in the proteome

Afterwards, the samples are mixed and processed; the peptide are analyzed by MS for protein identification and quantification

Ong and Mann, Nature Protocols, 2007

Quantification with labelling: iTRAQ

Quantitative proteomics

De novo peptide sequencing – Exercise

Derive an amino acid sequence from the idealized spectrum. The measured m/z of the doubly charged precursor ion is 1025.45 (average mass). Only peaks that correspond to either a b- or y-ion are indicated with their m/z, which means that peaks without numbers don't have to be taken into account. The error tolerance for the fragment ions is +/- 0.2 (except for finding the entry point where the tolerance is +/- 0.5). The total length of the correct sequence is 21 amino acids.
